model hypotheses, not diagnoses · no quantum-advantage claim

EEG → quantum state

2,000 voltages a second → 10 numbers

8 channels × 250 Hz, condensed into band powers

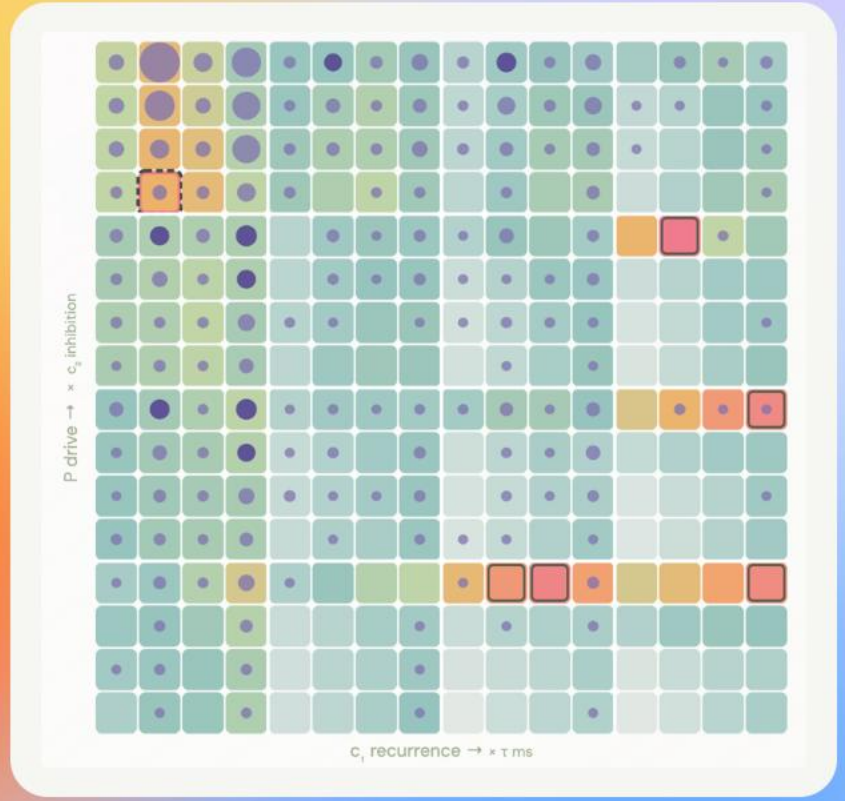

8 qubits hold all 256 possible brains

4 model dials × 2 qubits · a 2^8-dim Hilbert space $|\psi\rangle = \Sigma\ \alpha_i\ |i\rangle$

Your EEG decides which brains get louder

the mismatch becomes the circuit's energy; QAOA amplifies the best fits

Measure → re-simulate → verify

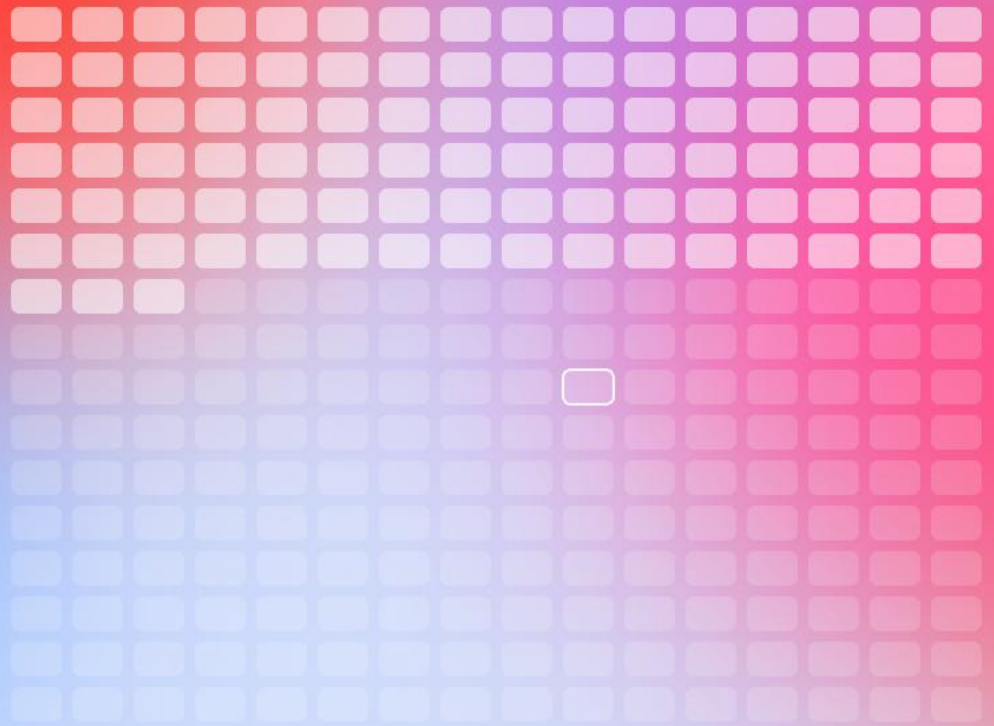

all 256 brains, scored against your EEG (from the app)

we encode hypotheses, not raw EEG · each extra bit per dial multiplies the space · no quantum-advantage claim at 256

Amplify, don’t scan

Classical · check one brain at a time

checked 99 / 256 · O(N)

Quantum · make the right one louder

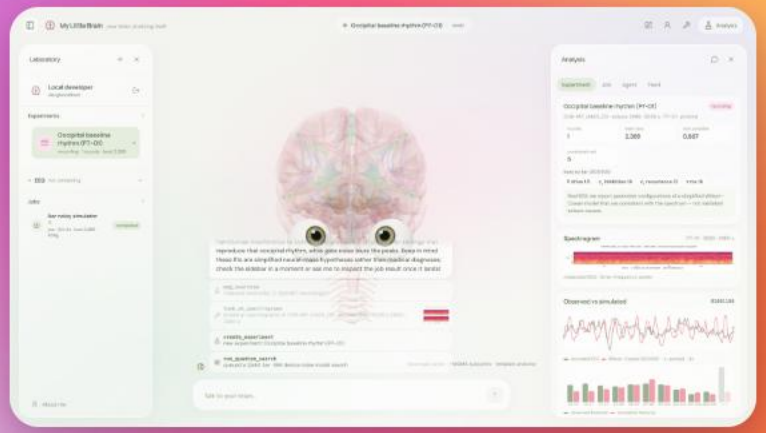

round 8 / 12 · P(right) = 76% · O(√N)

Grover amplitude amplification, exact for N = 256 · our QAOA uses the same interference heuristically — no speed-up claimed at 256

Behind the scenes

OpenBCI Ultracortex
